The acidity of the α -hydrogen of carbonyl compounds depends on the stability of the carbanion formed (which is the conjugate base in this case). If the carbanion is more stable, the α -hydrogen is more acidic. The carbanion can be stabilized either with resonance – i.e. the carbanion lone pair to the oxygen of the carbonyl to form the stabilized enolate, or by inductive effect – if electron withdrawing groups are directly attached to the α -carbon.

Reactions at the α -Carbon. Many aldehydes and ketones undergo substitution reactions at an α carbon, as shown in the following diagram (α -carbon atoms are colored blue). These reactions are acid or base catalyzed, but in the case of halogenation the reaction generates an acid as one of the products, and is therefore autocatalytic. If the α -carbon is a chiral center, as in the second example, the products of halogenation and isotopic exchange are racemic.

Since the negative charge of an enolate anion is delocalized over the α -carbon and the oxygen, as shown earlier, electrophiles may bond to either atom. Reactants having two or more reactive sites are called ambident, so this term is properly applied to enolate anions. Modestly electrophilic reactants such as alkyl halides are not sufficiently reactive to combine with neutral enol tautomers, but the increased nucleophilicity of the enolate anion conjugate base permits such reactions to ...

There are three hydrogens attached to that α carbon, we have three α protons, so our base could take any one of those three α protons. I'm just going to draw one in here to simplify things. And so we could show our base taking this proton and leaving these electrons behind on our carbon, so we can draw the enolate anion that would form.
