we subtract \$10 from each side. $20 = 2x$. simplify. $20 \div 2 = 2x \div 2$. divide both sides by 2 to isolate x . $10 = x$. x equals 10. We may purchase 10 books for \$30. When we want to solve an equation including one unknown variable, as x in the example above, we always aim at isolating the unknown variable.

Example: $y = 2x + 1$ is a linear equation: The graph of $y = 2x + 1$ is a straight line. When x increases, y increases twice as fast, so we need $2x$. When x is 0, y is already 1. So $+1$ is also needed. And so: $y = 2x + 1$. Here are some example values:

The cool thing about algebra is you can always get your answer and put it back into the original equation to make sure you are right. So the original equation was minus $\frac{3}{4}$ times x , and here we'll substitute the x back into the equation. Wherever we saw x , we'll now put our answer. So it's minus $\frac{40}{39}$, and our

original equation said that equals $\frac{10}{13}$.

In algebra, a quadratic equation (from the Latin quadratus for "square") is any equation that can be rearranged in standard form as $ax^2+bx+c=0$ where x represents an unknown, and a , b , and c represent known numbers, where $a \neq 0$. If $a = 0$, then the equation is linear, not quadratic, as there is no ax^2 term.

If $a = b$ then $a - c = b - c$ for any c . As with the last property we can subtract a number, c , from both sides of an equation. If $a = b$ then $ac = bc$ for any c . Like addition and subtraction, we can multiply both sides of an equation by a number, c , without changing the equation.
