Main Group Organometallic Chemistry - 1. Introduction.

Organometallic compounds have been known and studied for over 250 years. Many of these early compounds were prepared directly from the metal by oxidative addition of alkyl halides. All these metals have strong or moderately negative reduction potentials, with lithium and magnesium being the most reactive.

Main Group Organometallic Chemistry

The introductory chapter starts with giving the reader a compact but solid background on early main group organometallics (history, syntheses, bonding and structure, and solution dynamics) that form the foundation for the second part that deals with the fundamental steps in s-block metal catalysis. This short summary of working principles in catalysis is followed by a discussion on the mechanism of substrate activation by early main group metals.

The strong differences between transition metal complexes and highly polar early main group organometallics are reflected in their divergent hydrosilylation chemistry. A major advantage of alkene hydrosilylation with group 2 metal catalysts is their very high selectivity for the Markovnikov products.

With the exception of zinc and copper, the metal components of the organometallic reagents we have discussed above have been main-group metals. In most cases the reagents were used in stoichiometric quantities, and many had well defined constitutions, although oligomeric clustering was solvent dependent.

Transmetallation is the major process by which main group organometallic complexes can be incorporated into the reaction

manifold of transition metal organometallics. The general process involves transfer of an R group from a main group metal to a transition metal (Equation (5)). Although the process is not well understood, when it is part of a transition metal catalyzed process, it is often the rate-limiting step.
