The Canny edge detector is an edge detection operator that uses a multi-stage algorithm to detect a wide range of edges in images. It was developed by

John F. Canny in 1986. Canny also produced a computational theory of edge detection explaining why the technique works.

Edges are found in the image using Verilog HDL with Modelsim software and final image value is stored in another file. By using the Matlab program the edge detected images values are converted into Image. This level is up to the simulation process. To implement in FPGA the interface coding to be written for VGA display.

EDGE DETECTION SYSTEMS - Verilog Course Team

A positive edge detector will send out a

pulse whenever the signal it is monitoring changes from 0 to 1 (positive edge). Design The idea behind a positive edge detector is to delay the original signal by one clock cycle, take its inverse and perform a logical AND with the original signal.

Verilog Positive Edge Detector - ChipVerify

Since the sobel-edge detection unit receives only a single 8-bit pixel when the `i_valid` signal is high, the unit must be able to store the first eight 8-bit pixels until the 9th pixel is received. The key idea of the memory module is the program counter, PC, which is incremented for every pixel received (when `i_valid` has a rising edge).

Description Canny edge detector with a 9x9 mask (gradient + gaussian filtering with $\sigma = \sqrt{2}$). Able to produce a throughput of 1 pixel per clock cycle. Successfully implemented on a Virtex4 up to 300Mhz clock frequency.

In this project we are going to look at how we can build a Sobel edge detection IP core using HLS and then include it within the Xilinx FPGA of our choice. The selected device could be a traditional FPGA such as a Spartan Seven or Artix, alternatively it could also be implemented within the programmable logic of a heterogeneous SoC like the

Zynq 7000 or Zynq MPSoC.
