Targeting DNA methylation for cancer therapy has had a rocky history. The first reports on DNA methylation changes in cancer described global loss of methylation, which has been suggested to drive tumorigenesis through activation of oncogenic proteins or induction of chromosomal instability. In this context, reducing DNA methylation was viewed as a tumor-promoting event rather than a promising ...

Abstract. DNA methylation patterns are frequently altered in cancer cells as compared to normal cells. A large body of research associates these DNA methylation aberrations with cancer initiation and progression. Moreover, cancer cells seem to depend upon these aberrant DNA methylation profiles to thrive. Finally, DNA methylation modifications are reversible, highlighting the potential to target the global methylation patterns for cancer therapy.

DNA methylation patterns in the colonic tissues of a subset of colon cancer patients were evaluated. Information on DNA methylation in the normal colonic tissues was available on 234 colon cancer patients (164 never/ex-HT users and 70 current HT users; Table IV). On the basis that current HT users had lower risk of colon cancer, we treated 'current HT users' as 'exposed' and 'never/ex-HT users' as 'non-exposed' in these analyses.
