Conductive anodic filament (CAF) formation was first reported in 1976. This electrochemical failure mode of electronic substrates involves the growth of a copper-containing filament subsurface along the epoxy-glass interface, from anode to cathode. Despite the projected lifetime reduction due to CAF, field failures were not identified in the 1980s. Recently, however, field failures of critical equipment have been reported.

PCB reliability problems due to the growth of CAF ...

Catastrophic electrical failure only occurs when the filament of copper salts bridge the anode and cathode in question. Under humid conditions the salts are conductive and will allow a massive increase in current flow between the previously well-isolated copper areas and consequently circuit failure occurs.

The CAF Mechanism

One failure mechanism of particular concern is conductive anodic filament formation, which typically occurs in two steps: degradation of the resin/glass fiber bond followed by an electrochemical reaction. The glass-resin bond degradation provides a path along

which electrodeposition occurs due to electrochemical reactions.

Conductive anodic filament (CAF) failure is copper corrosion within a printed board. It is electro-migration of the copper from anode to cathode between two conductors of different potential. A combination of bias voltage and high humidity enhances CAF failures. When a filament grows between electrically isolated nets, electrical failure results.
