The rate of decay is a fixed rate called a half-life. The half-life of a radioactive isotope refers to the amount of time required for half of a quantity of a radioactive isotope to decay. Carbon-14 has a half-life of 5730 years, which means that if you take one gram of carbon-14, half of it will decay in 5730 years. Different isotopes have different

half-lives.

The half-life of an element is the time it takes half of the radioactive. atoms to decay. Half-life is defined as; "The time required for half of any given amount. of a radioactive substance (Parent Atoms) to decay into another substance. (Daughter Atoms)". Radioactive decay is a constant process where the unstable.

Explain your answer. Half-life means that half of a sample decays after one half-life and the rest of the sample decays after the next half-life. One reason it is important to know the half-life of a sample is to safely dispose of radioactive waste, which is usually stored for 10 half-lives.

The half-life of an isotope can be explained as the average time that takes half of the total number of atoms in a sample to decay eventually. What this experiment aims to show is how probability is related to radioactive decay. We use coins in this experiment as a model that reflects the randomness of the radioactive decay process.

 1. Hypothesize what half-life is: Half-life is the amount of time it takes for approximately half of the radioactive atoms in a sample to decay into a more stable form. Every radioactive element has a different half-life. 2. Calculate the number of radioactive atoms remaining after each half-life.

Half-Life Data-Teacher Answer Key

1) Determine the average number of atoms remaining (not decayed) at each three-second time interval by adding the results from the two trials and dividing by two. 2) Create a table that compares time to the average number of atoms remaining at each time interval.
