For porosity measurement, a valve downstream of the plug sample is closed while, for permeability measurement, it is opened as helium flows from the reference tank through the sample. The core plug is loaded automatically via a carousel into the test coreholder which is designed for confining stresses of up to 10,000 psi.

Porosity is a measure of the reservoir storage capacity. It is defined as the void volume (pore volume) of a sample divided by its bulk volume. It enters most equations as a fraction and is reported in core analysis studies as a percent. It varies from less than 10% to greater than 40% in sandstones and from 5% to 25% in limestones and dolomites.

[Formation Evaluation] The set of measurements normally carried out on core plugs or whole core. These generally include porosity, grain density, horizontal permeability, fluid saturation and a lithologic description. Routine core analyses often include a core gamma log and measurements of vertical permeability.

CORE POROSITY BASICS Porosity is an

intrinsic property of reservoir rocks and indicates the storage capacity of the reservoir. It is used as a primary indicator of reservoir quality, and along with a few other factors, to calculate hydrocarbon volume in place, and recoverable reserves.
