Root Mean Square Error (RMSE) is the standard deviation of the residuals (prediction errors). Residuals are a measure of how far from the regression line data points are; RMSE is a measure of

how spread out these residuals are. In other words, it tells you how concentrated the data is around the line of best fit.

One way to assess how "good" our model fits a given dataset is to calculate the root mean square error, which is a metric that tells us how far apart our predicted values are from our observed values, on average. The formula to find the root mean square error, more commonly referred to as RMSE, is as follows: $RMSE = \sqrt{\frac{\sum (P_i - O_i)^2}{n}}$

RMSE is exactly what's defined. \$24.5 is the square root of the average of squared differences between your prediction and your actual observation. Taking squared differences is more common than absolute difference in statistics, as you might have learnt from the classical linear regression. It confuses me a little.

Interpreting the Root Mean Squared Error (RMSE)!

The root-mean-square deviation or root-mean-square error is a frequently used measure of the differences between values predicted by a model or an estimator and the values observed. The RMSD represents the square root of the second sample moment of the differences between predicted values and observed values or the quadratic mean of these differences. These deviations are called residuals when the calculations are performed over the data sample that was used for estimation and are called errors

Definition and basic properties. The MSE either assesses the quality of a predictor (i.e., a function mapping arbitrary inputs to a sample of values of some random variable), or of an estimator (i.e., a mathematical function mapping a sample of data to an estimate of a parameter of the population from which the data is sampled). The definition of an MSE differs according to whether one is ...
